Chapter 1

Introduction

Welcome to English 3844: Writing and Digital Media! In this class we write blogs, create podcasts and videos, and then curate all of this content on our own websites.

This booklet contains instructions and resources related to English 3844: Writing and Digital Media. Inside you'll find instructions on how to install and use Atom text editor, GitHub Desktop, and GitHub pages, as well as a few readings and a collection of audio and video development resources.

I'll add more and more content to this booklet as the semester progresses.

Chapter 2

Readings and resources

We won't have many readings this semester, but I have compiled a few excerpts from longer works below.

2.1 From “The Rhetorical Situation” by Lloyd Bitzer (1968)

The study of rhetoric dates back thousands of years, predating even Socrates. Since then, countless scholars have tried to answer the question, “What makes discourse rhetorical?” Lloyd Bitzer offered one of the clearest answers to that question in 1968. Below is a collection of excerpts from his essay “The Rhetorical Situation”.

Rhetoric alters reality

In order to clarify rhetoric-as-essentially-related-to-situation, we should acknowledge a viewpoint that is commonplace but fundamental: a work of rhetoric is pragmatic; it comes into existence for the sake of something beyond itself; it functions ultimately to produce action or change in the world; it performs some task. In short, rhetoric is a mode of altering reality, not by the direct application of energy to objects, but by the creation of discourse which changes reality through the mediation of thought and action. The rhetor alters reality by bringing into existence a discourse of such a character that the audience, in thought and action, is so engaged that it becomes mediator of change. In this sense rhetoric is always persuasive.

The rhetorical situation

Let us now amplify the nature of situation by providing a formal definition and examining constituents. Rhetorical situation may be defined as a complex of persons, events, objects, and relations presenting an actual or potential exigence which can be completely or partially removed if discourse, introduced into the situation, can so constrain human decision or action as to bring about the significant modification of the exigence. Prior to the creation and presentation of discourse, there are three constituents of any rhetorical situation: the first is the exigence; the second and third are elements of the complex, namely the audience to be constrained in decision and action, and the constraints which influence the rhetor and can be brought to bear upon the audience. Any exigence is an imperfection marked by urgency; it is a defect, an obstacle, something waiting to be done, a thing which is other than it should be.

Exigence

In any rhetorical situation there will be at least one controlling exigence which functions as the organizing principle: it specifies the audience to be addressed and the change to be effected. The exigence may or may not be perceived clearly by the rhetor or other persons in the situation; it may be strong or weak depending upon the clarity of their perception and the degree of their interest in it; it may be real or unreal depending on the facts of the case; it may be important or trivial; it may be such that discourse can completely remove it, or it may persist in spite of repeated modifications; it may be completely familiar - one of a type of exigences occurring frequently in our experience - or it may be totally new, unique. When it is perceived and when it is strong and important, then it constrains the thought and action of the perceiver who may respond rhetorically if he is in a position to do so.

Audience

The second constituent is the audience. Since rhetorical discourse produces change by influencing the decision and action of persons who function as mediators of change, it follows that rhetoric always requires an audience - even in those cases when a person engages himself or ideal mind as audience. It is clear also that a rhetorical audience must be distinguished from a body of mere hearers or readers: properly speaking, a rhetorical audience consists only of those persons who are capable of being influenced by discourse and of being mediators of change.

Constraints

Besides exigence and audience, every rhetorical situation contains a set of constraints made up of persons, events, objects, and relations which are parts of the situation because they have the power to constrain decision and action needed to modify the exigence. Standard sources of constraint include beliefs, attitudes, documents, facts, traditions, images, interests, motives and the like; and when the orator enters the situation, his discourse not only harnesses constraints given by situation but provides additional important constraints - for example his personal character, his logical proofs, and his style. There are two main classes of constraints: (1) those originated or managed by the rhetor and his method (Aristotle called these “artistic proofs”), and (2) those other constraints, in the situation, which may be operative (Aristotle’s “inartistic proofs”).

2.2 From “As We May Think” by Vannevar Bush (1945)

Vannevar Bush played a key role in military research and development during WWII, including the development of the atomic bomb. He also kind of invented the concept of the hyperlink decades before personal computing and the web became realities. (He even predicted we would all walk around with our own personal cameras—not in our pockets, but on our heads!)

In the excerpt from “As We May Think” (1945) below, Bush outlines his vision for a personal computer containing vast amounts of information.

Pay special attention to his thoughts on mental association and trails, as these concepts can teach us a ton about writing in and for digital media. Consider how you can use the ideas of the “associative web” and the link to help (a) tie your project together and (b) advocate for your group’s cause. How can you connect your blogs, podcasts, and videos together? How can you connect everything you make to the larger conversation about your topic?

The human mind and association

The real heart of the matter of selection, however, goes deeper than a lag in the adoption of mechanisms by libraries, or a lack of development of devices for their use. Our ineptitude in getting at the record is largely caused by the artificiality of systems of indexing. When data of any sort are placed in storage, they are filed alphabetically or numerically, and information is found (when it is) by tracing it down from subclass to subclass. It can be in only one place, unless duplicates are used; one has to have rules as to which path will locate it, and the rules are cumbersome. Having found one item, moreover, one has to emerge from the system and re-enter on a new path.

The human mind does not work that way. It operates by association. With one item in its grasp, it snaps instantly to the next that is suggested by the association of thoughts, in accordance with some intricate web of trails carried by the cells of the brain. It has other characteristics, of course; trails that are not frequently followed are prone to fade, items are not fully permanent, memory is transitory. Yet the speed of action, the intricacy of trails, the detail of mental pictures, is awe-inspiring beyond all else in nature.

Man cannot hope fully to duplicate this mental process artificially, but he certainly ought to be able to learn from it. In minor ways he may even improve, for his records have relative permanency. The first idea, however, to be drawn from the analogy concerns selection. Selection by association, rather than indexing, may yet be mechanized. One cannot hope thus to equal the speed and flexibility with which the mind follows an associative trail, but it should be possible to beat the mind decisively in regard to the permanence and clarity of the items resurrected from storage.

Figure 2.1: Memex machine

The memex machine

Consider a future device for individual use, which is a sort of mechanized private file and library. It needs a name, and, to coin one at random, “memex” will do. A memex is a device in which an individual stores all his books, records, and communications, and which is mechanized so that it may be consulted with exceeding speed and flexibility. It is an enlarged intimate supplement to his memory.

It consists of a desk, and while it can presumably be operated from a distance, it is primarily the piece of furniture at which he works. On the top are slanting translucent screens, on which material can be projected for convenient reading. There is a keyboard, and sets of buttons and levers. Otherwise it looks like an ordinary desk.

In one end is the stored material. The matter of bulk is well taken care of by improved microfilm. Only a small part of the interior of the memex is devoted to storage, the rest to mechanism. Yet if the user inserted 5000 pages of material a day it would take him hundreds of years to fill the repository, so he can be profligate and enter material freely.

Most of the memex contents are purchased on microfilm ready for insertion. Books of all sorts, pictures, current periodicals, newspapers, are thus obtained and dropped into place. Business correspondence takes the same path. And there is provision for direct entry. On the top of the memex is a transparent platen. On this are placed longhand notes, photographs, memoranda, all sorts of things. When one is in place, the depression of a lever causes it to be photographed onto the next blank space in a section of the memex film, dry photography being employed.

There is, of course, provision for consultation of the record by the usual scheme of indexing. If the user wishes to consult a certain book, he taps its code on the keyboard, and the title page of the book promptly appears before him, projected onto one of his viewing positions.

Frequently-used codes are mnemonic, so that he seldom consults his code book; but when he does, a single

tap of a key projects it for his use. Moreover, he has supplemental levers. On deflecting one of these levers to the right he runs through the book before him, each page in turn being projected at a speed which just allows a recognizing glance at each. If he deflects it further to the right, he steps through the book 10 pages at a time; still further at 100 pages at a time. Deflection to the left gives him the same control backwards.

A special button transfers him immediately to the first page of the index. Any given book of his library can thus be called up and consulted with far greater facility than if it were taken from a shelf. As he has several projection positions, he can leave one item in position while he calls up another. He can add marginal notes and comments, taking advantage of one possible type of dry photography, and it could even be arranged so that he can do this by a stylus scheme, such as is now employed in the telautograph seen in railroad waiting rooms, just as though he had the physical page before him.

Associative indexing

All this is conventional, except for the projection forward of present-day mechanisms and gadgetry. It affords an immediate step, however, to associative indexing, the basic idea of which is a provision whereby any item may be caused at will to select immediately and automatically another. This is the essential feature of the memex. The process of tying two items together is the important thing.

When the user is building a trail, he names it, inserts the name in his code book, and taps it out on his keyboard. Before him are the two items to be joined, projected onto adjacent viewing positions. At the bottom of each there are a number of blank code spaces, and a pointer is set to indicate one of these on each item. The user taps a single key, and the items are permanently joined. In each code space appears the code word. Out of view, but also in the code space, is inserted a set of dots for photocell viewing; and on each item these dots by their positions designate the index number of the other item.

Thereafter, at any time, when one of these items is in view, the other can be instantly recalled merely by tapping a button below the corresponding code space. Moreover, when numerous items have been thus joined together to form a trail, they can be reviewed in turn, rapidly or slowly, by deflecting a lever like that used for turning the pages of a book. It is exactly as though the physical items had been gathered together from widely separated sources and bound together to form a new book. It is more than this, for any item can be joined into numerous trails.

The owner of the memex, let us say, is interested in the origin and properties of the bow and arrow. Specifically he is studying why the short Turkish bow was apparently superior to the English long bow in the skirmishes of the Crusades. He has dozens of possibly pertinent books and articles in his memex. First he runs through an encyclopedia, finds an interesting but sketchy article, leaves it projected. Next, in a history, he finds another pertinent item, and ties the two together. Thus he goes, building a trail of many items. Occasionally he inserts a comment of his own, either linking it into the main trail or joining it by a side trail to a particular item. When it becomes evident that the elastic properties of available materials had a great deal to do with the bow, he branches off on a side trail which takes him through textbooks on elasticity and tables of physical constants. He inserts a page of longhand analysis of his own. Thus he builds a trail of his interest through the maze of materials available to him.

And his trails do not fade. Several years later, his talk with a friend turns to the queer ways in which a people resist innovations, even of vital interest. He has an example, in the fact that the outraged Europeans still failed to adopt the Turkish bow. In fact he has a trail on it. A touch brings up the code book. Tapping a few keys projects the head of the trail. A lever runs through it at will, stopping at interesting items, going off on side excursions. It is an interesting trail, pertinent to the discussion. So he sets a reproducer in action, photographs the whole trail out, and passes it to his friend for insertion in his own memex, there to be linked into the more general trail.

Wholly new forms

Wholly new forms of encyclopedias will appear, ready made with a mesh of associative trails running through them, ready to be dropped into the memex and there amplified. The lawyer has at his touch the associated opinions and decisions of his whole experience, and of the experience of friends and authorities. The patent attorney has on call the millions of issued patents, with familiar trails to every point of his client's interest. The physician, puzzled by a patient's reactions, strikes the trail established in studying an earlier similar

case, and runs rapidly through analogous case histories, with side references to the classics for the pertinent anatomy and histology. The chemist, struggling with the synthesis of an organic compound, has all the chemical literature before him in his laboratory, with trails following the analogies of compounds, and side trails to their physical and chemical behavior.

2.3 How Google search works

Vannevar Bush dreamed of a “mesh of associative trails” and of “associative indexing” that would help users navigate information structures. That mesh is now a web—the web. Sergey Brin and Larry Page indexed that web when they created Google. They weren’t the first to index the web, but they did conceive an algorithm that provided better results than any other search engine.

The video and reading below should help you understand why links are so crucial to any web content creator. The video comes from Google’s How Search Works page, while the reading comes from The Anatomy of a Large-Scale Hypertextual Web Search Engine, a paper Brin and Page wrote as Stanford graduate students.

How search works

Pay special attention to the importance of Google’s “PageRank” formula at about 1:30.

From “The Anatomy of a Large-Scale Hypertextual Web Search Engine” by Sergey Brin and Lawrence Page (1998)

The Google search engine has two important features that help it produce high precision results. First, it makes use of the link structure of the Web to calculate a quality ranking for each web page. This ranking is called PageRank and is described in detail in [Page 98]. Second, Google utilizes link to improve search results.

PageRank: Bringing Order to the Web

The citation (link) graph of the web is an important resource that has largely gone unused in existing web search engines. We have created maps containing as many as 518 million of these hyperlinks, a significant sample of the total. These maps allow rapid calculation of a web page’s “PageRank”, an objective measure of its citation importance that corresponds well with people’s subjective idea of importance. Because of this correspondence, PageRank is an excellent way to prioritize the results of web keyword searches. For most popular subjects, a simple text matching search that is restricted to web page titles performs admirably when PageRank prioritizes the results (demo available at google.stanford.edu). For the type of full text searches in the main Google system, PageRank also helps a great deal.

Description of PageRank Calculation

Academic citation literature has been applied to the web, largely by counting citations or backlinks to a given page. This gives some approximation of a page’s importance or quality. PageRank extends this idea by not counting links from all pages equally, and by normalizing by the number of links on a page. PageRank is defined as follows:

We assume page A has pages T1...Tn which point to it (i.e., are citations). The parameter d is a damping factor which can be set between 0 and 1. We usually set d to 0.85. There are more details about d in the next section. Also C(A) is defined as the number of links going out of page A. The PageRank of a page A is given as follows:

$$PR(A) = (1-d) + d (PR(T1)/C(T1) + \dots + PR(Tn)/C(Tn))$$

Note that the PageRanks form a probability distribution over web pages, so the sum of all web pages’ PageRanks will be one.

Intuitive Justification

PageRank can be thought of as a model of user behavior. We assume there is a “random surfer” who is given a web page at random and keeps clicking on links, never hitting “back” but eventually gets bored and

starts on another random page. The probability that the random surfer visits a page is its PageRank. And, the d damping factor is the probability at each page the “random surfer” will get bored and request another random page. One important variation is to only add the damping factor d to a single page, or a group of pages. This allows for personalization and can make it nearly impossible to deliberately mislead the system in order to get a higher ranking. We have several other extensions to PageRank, again see [Page 98].

Another intuitive justification is that a page can have a high PageRank if there are many pages that point to it, or if there are some pages that point to it and have a high PageRank. Intuitively, pages that are well cited from many places around the web are worth looking at. Also, pages that have perhaps only one citation from something like the Yahoo! homepage are also generally worth looking at. If a page was not high quality, or was a broken link, it is quite likely that Yahoo’s homepage would not link to it. PageRank handles both these cases and everything in between by recursively propagating weights through the link structure of the web.

Anchor Text

The text of links is treated in a special way in our search engine. Most search engines associate the text of a link with the page that the link is on. In addition, we associate it with the page the link points to. This has several advantages. First, anchors often provide more accurate descriptions of web pages than the pages themselves. Second, anchors may exist for documents which cannot be indexed by a text-based search engine, such as images, programs, and databases. This makes it possible to return web pages which have not actually been crawled. Note that pages that have not been crawled can cause problems, since they are never checked for validity before being returned to the user. In this case, the search engine can even return a page that never actually existed, but had hyperlinks pointing to it. However, it is possible to sort the results, so that this particular problem rarely happens.

This idea of propagating anchor text to the page it refers to was implemented in the World Wide Web Worm [McBryan 94] especially because it helps search non-text information, and expands the search coverage with fewer downloaded documents. We use anchor propagation mostly because anchor text can help provide better quality results. Using anchor text efficiently is technically difficult because of the large amounts of data which must be processed. In our current crawl of 24 million pages, we had over 259 million anchors which we indexed.

Other Features

Aside from PageRank and the use of anchor text, Google has several other features. First, it has location information for all hits and so it makes extensive use of proximity in search. Second, Google keeps track of some visual presentation details such as font size of words. Words in a larger or bolder font are weighted higher than other words. Third, full raw HTML of pages is available in a repository.

2.4 Dark Patterns

Dark patterns are design strategies used by content developers to trick you into taking some action you wouldn’t otherwise take. You have certainly encountered dark patterns before, but you (a) may not have recognized them as manipulative or (b) may not have realized that these patterns are indeed patterns—once you recognize them, you’ll see variations all over the web.

Check out the video below and then visit the Dark Patterns website.

2.5 BuzzFeed’s formula

This article is from 2014, which is in some respects a long time ago. But the core insights of BuzzFeed’s video formula, excerpted below, will still resonate with most anyone who has ever blown a couple hours taking BuzzFeed quizzes.

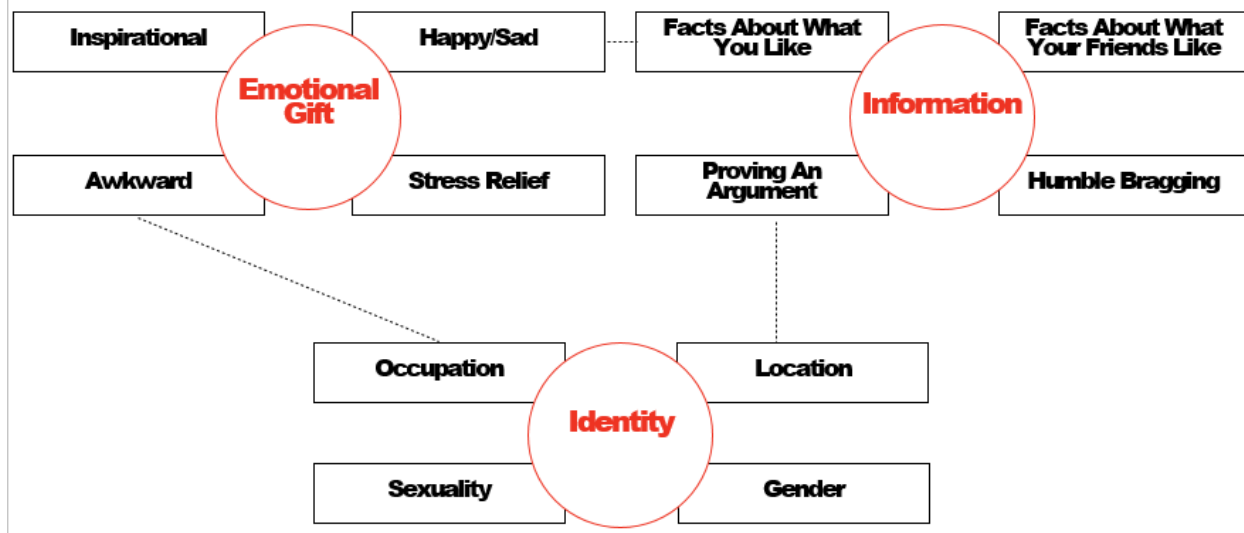

Figure 2.2: BuzzFeed content categories

Of particular note are BuzzFeed's "pillars of content": "emotional gift," "information," and "identity." These pillars ensure that BuzzFeed creates not just consumable content, but sharable content.

Emotional Gift: This type of content taps into the vast range of human emotions. A BuzzFeed video should be able to change your mood from a sad to a happy one, it should be able to relieve stress, and give the viewer respite from upsetting personal, or even world events. The whole point of the video content is to make the viewer feel something – if they feel it, they will share it.

Information: Can you present information in a new, interesting way? Never underestimate the power of the humble brag – give the viewer the impression that they were aware of most of the facts, but were genuinely happy to learn a couple more. Also, great informational videos can help prove or disprove an argument, and that makes them fantastically shareable.

Identity: This is huge, and demonstrated by just how popular the BuzzFeed quizzes are. People want to to be identified as something, to belong to a group, and taking the BuzzFeed quizzes is one way of confirming where they belong. Or not, in some cases. But it's all good because it all leads to that content being shared.

Chapter 3

Atom

3.1 Introducing Atom

Atom is a text editor. A text editor is a little bit like Microsoft Word, but for coding. With a little setup and practice, however, you may find yourself writing your English papers in Atom instead of Word. Atom is faster, simpler, prettier, and does most of what you need in terms of text production. At the very least, it's *much* better than Word for taking notes and writing things for the internet.

We'll eventually use it to code websites, but first we'll use it for writing blog posts. So let's install it and customize it for those tasks.

This process might be a little scary, but do the best you can. I'll include some links to help you if you get stuck.

3.2 Installing Atom

First, let's install the program and put it where it belongs on your computer.

1. If you don't have **Google Chrome** on your computer, download it. You don't *technically* need Chrome, but it's what we'll use to examine code later in the semester.
2. Open Chrome and go to atom.io. You should see a screen like the one below.

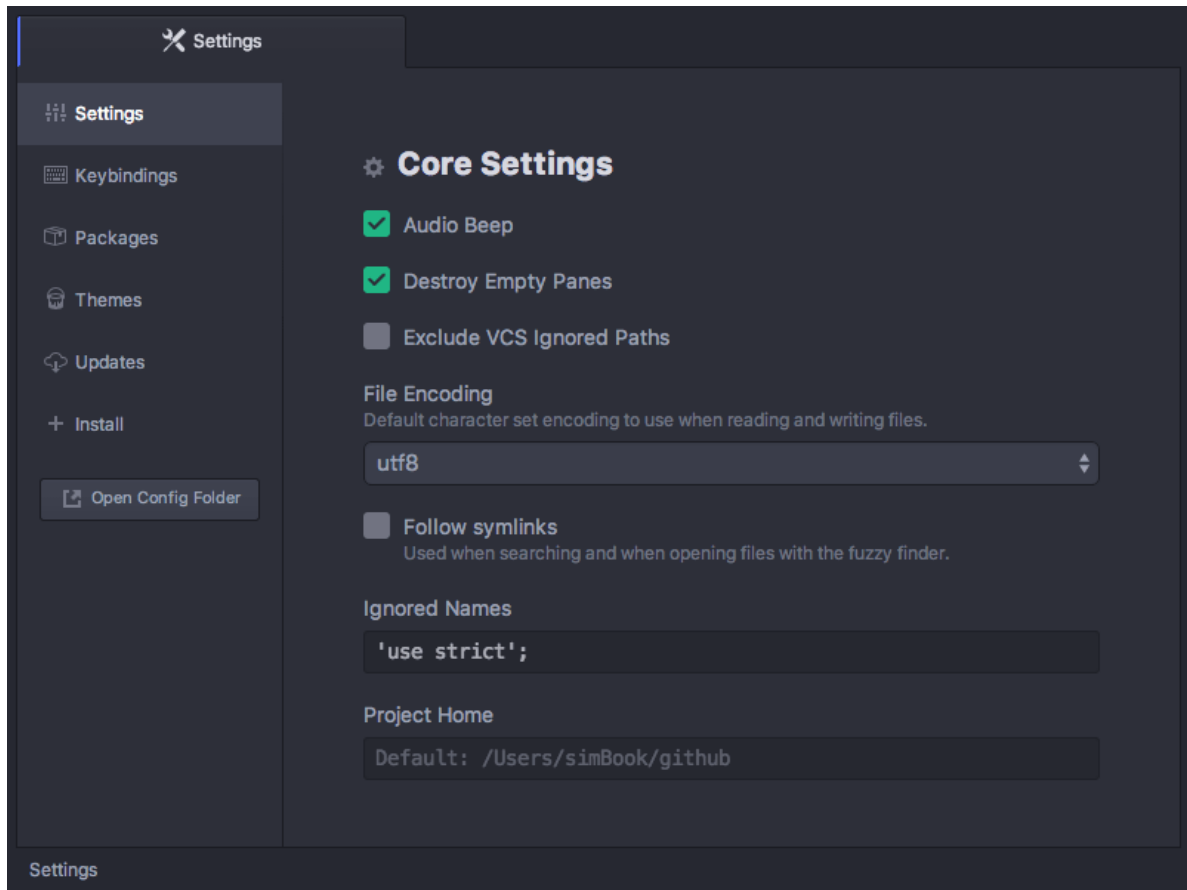

3. See the **Download** button? Click it. Your computer should then download a .zip (Mac) or .exe (Win) file. Some computers may automatically open and unpack the .zip file. If yours doesn't, then open the .zip file yourself. (If you don't know how to open .zip files on your computer, Google it.) Eventually, you should see the Atom icon.
4. If you're using a Mac, drag that icon to your **Applications** folder. If you're using Windows, Atom should automatically add an Atom shortcut to your **desktop** and your **Start menu**.
5. Click the Atom icon to launch Atom!

For more info/help, visit the Installing Atom section of the Atom documentation. Note that at the top of the page you can choose your operating system (Windows or Mac).

3.3 Setting up Atom and installing packages

Atom's a little different than Word. Word comes with a whole bunch of features, most of which you'll never use. Atom comes with a few features but allows you to quickly install many more. You install those features via the **package manager**. Let's install most of the packages we'll need this semester. While we're at it, we'll adjust some other settings to make Atom a more comfortable writing environment.

1. Once you've launched Atom, you should see a screen with a Welcome Guide and other information. At the top of the screen, you should see a menu bar like you do with other applications (File, Edit, View, etc.). Open the Settings view by choosing **File => Settings (Win)** or **Atom => Preferences (Mac)**. Alternatively, if you want to be a baller, just hit **ctrl+comma (Win)** or **cmd+comma (Mac)**. You should see a screen like the one below.

2. First, click the Editor tab, scroll down to **Soft Wrap**, and check the corresponding box.
3. Next, click the Themes tab. Here you can choose a dark background or a light background. If you prefer a dark background, do nothing. If you prefer a light background, choose One Light. Be sure to change both the UI Theme and the Syntax Theme.
4. Finally, click the Install tab. You should see a screen like the one below.

5. In the Install Packages search bar, search for **atom-beautify**. When the package appears, click the **Install** button and wait for the installation to complete. Congrats—you’ve just installed a package!
6. Repeat step 5 for each of the packages below. Once you’ve installed the packages, you can view some of them in the Packages menu (in the same menu bar as File, Edit, View, etc.).
 - **atom-html-preview** – allows you to view changes to your website from within Atom
 - **emmet** – allows you to write your code more quickly
 - **linter** – helps identify potential errors in your code. When you install this one, Atom may ask you to install “dependencies.” Allow each of these
 - **markdown-writer** – allows you to make pretty documents with no fuss (we’ll use this one right away!)
 - **tool-bar** – with the next package, adds a toolbar with buttons for italics, etc.
 - **tool-bar-markdown-writer** – see directly above
 - **pandoc-convert** – converts Markdown files (see below) to Word docs, PDFs, or other formats

3.4 Optional packages

If you wish, you may also download these packages:

- **wordcount** – adds a word count to the bottom of Atom’s interface
- **linter-write-good** – tries to identify common writing issues (e.g., passive voice). Can be helpful, but when in doubt use your own judgment.

3.5 Command Palette

You can do pretty much anything in Atom—open files, install packages, convert files from one type to another—via the Command Palette. To open the palette, type **cmd+shift+p** (Mac) or **ctrl+shift+p** (Win).

Now type whatever you want to do (e.g., open file, change theme, spell check) and select the option you want. At first you may struggle to figure out the right thing to type, but after some practice, using the Command Palette will be much faster than clicking through the various menus and submenus (though you can always do that, too!).

Chapter 4

Markdown

Markdown is a lightweight markup language, which basically means that it allows you to easily create italics, boldface, links, images, and bulleted/numbered lists. Markdown is faster than Word for most kinds of writing, but the best part is that a Markdown file can become a Word doc, a PDF, an HTML file, a slide show, an MLA document—whatever!

You can find a Markdown tutorial at CommonMark.

4.1 Create a Markdown file

Make your first Markdown file in Atom by following the steps below.

1. In Atom, choose **File => New file**.
2. Save the file as a Markdown file by choosing **File => Save**. Name the file `markdown-test.md`. Be sure to use the **.md** suffix.
3. Paste the text below into the file, then save the file.

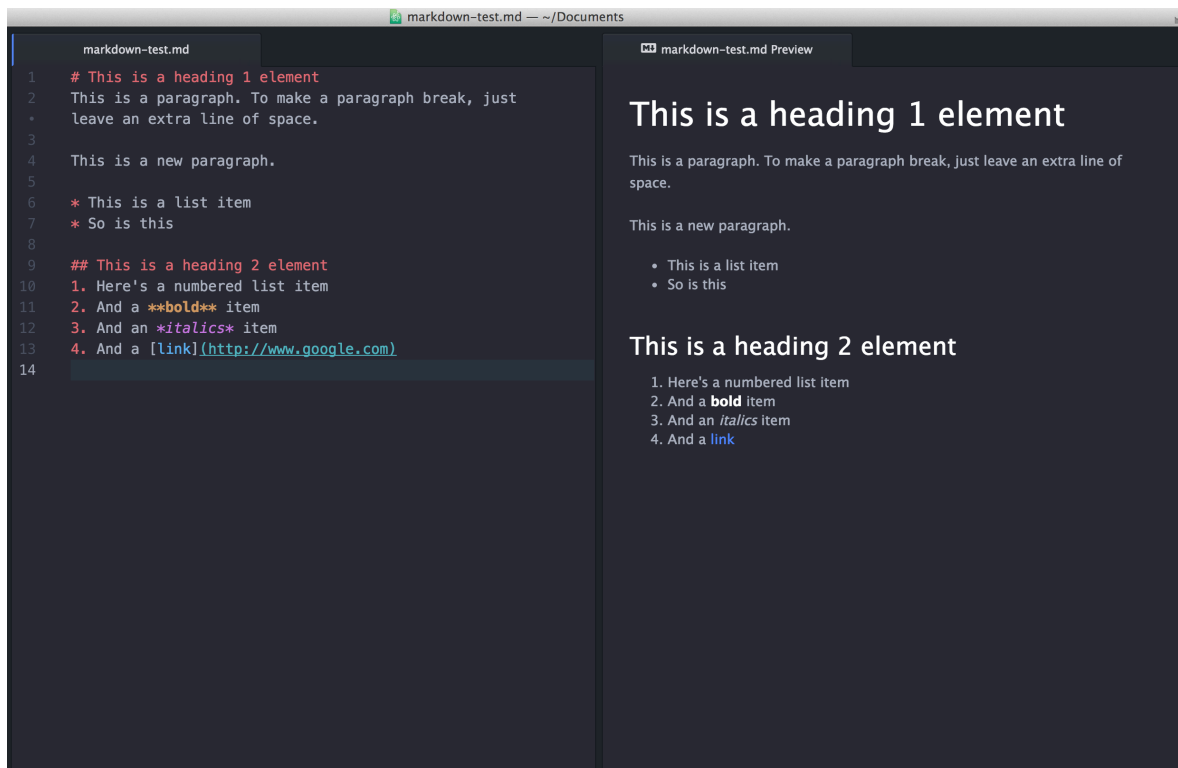

```
# This is a heading 1 element
This is a paragraph. To make a paragraph break, just leave an extra line of space.

This is a new paragraph.

* This is a list item
* So is this

## This is a heading 2 element
1. Here's a numbered list item
2. And a bold item
3. And an italics item
4. And a [link](http://www.google.com)
```

4. Now, to see the output, look for the Packages menu in the menu bar (File, Edit, View, etc.) at the top of the screen. Click Packages, then choose Markdown Preview. You should see a preview window like the one below.

5. That's it! Markdown is that simple. If you want to learn more, use the Markdown cheat sheet. Soon, we'll learn how to convert Markdown to a nice pdf or html document—and how to paste perfectly formatted writing into emails, newsletters, Google or Word docs, and more.

4.2 Convert Markdown to HTML, Word, or PDF formats

Markdown's greatest feature is that Markdown content can become pretty much any other kind of content. Your Markdown can become a web page, a Word doc, a PDF, an MLA paper, an ebook (like this one!), a slideshow—whatever.

HTML

HTML is the language of most web pages. Generally, each web page on a site consists of a single `.html` file. To convert your Markdown into HTML,

1. In Atom, make sure you're viewing your Markdown file. Open Markdown Preview by selecting **Packages => Markdown Preview => Toggle Preview**.
2. Right-click some blank space in the preview window and select **Save As HTML**. Atom will give you the options of renaming your file and selecting a save location. Be sure the filename ends in `.html` (if you see something like `filename.md.html`, you can delete the `.md` part). Save it to your documents folder (or wherever).
3. Find your new HTML file on your computer, and double-click it to open it in your web browser. If you want to view or edit the HTML file, simply open it in Atom!

Pasting HTML into Medium

In most cases, you can paste your HTML into Medium with no errors. Simply open the HTML file in your browser (step 3 above), then copy the entire document to your clipboard. Paste the copied content into the Medium editor.

Word or PDF

To convert your Markdown to Word or PDF format, you'll need Atom's **pandoc-convert** package. See

Setting up Atom and installing packages. To convert your Markdown,

1. In Atom, make sure you're viewing your Markdown file.
2. Press **cmd+shift+p** (Mac) or **ctrl+shift+p** (Win) to open the Command Palette.
3. In the Command Palette textbox, type **pandoc docx** (for Word) or **pandoc pdf** (for PDF). When you see the option you want, click the option or press return.
4. Atom will give you the options of renaming your file and selecting a save location. Be sure the filename ends in **.docx** or **.pdf** (if you see something like **filename.md.docx**, you can delete the **.md** part). Save it to your documents folder (or wherever).
5. Find the new Word or PDF doc on your computer and open it!

NOTE: some people have reported problems converting to PDF format. You may be able to fix this problem by downloading LaTeX, a document preparation system. If you don't anticipate using Markdown outside of this course, then you can skip this step and simply convert to Word format instead.

MLA

Want to achieve perfect MLA formatting every time? Try markdowntomla.com!

You can also use Markdown to make slide decks *way* faster than you could with PowerPoint. Deckdown is a good place to start, but once we learn HTML and GitHub, we can add images, videos, etc.

4.3 Cheat sheet

This cheat sheet comes from Matt Cone at markdownguide.org. You can also find a cheat sheet within Atom by clicking **Packages => Markdown Writer => Open Cheat Sheet**.
